Japanese Encephalitis Virus, Okayama *Culex tritaeniorhynchus* (OCT)-541, Line 35-24

**Catalog No. NR-91**
(Derived from ATCC® VR-343™)

For research use only. Not for human use.

**Contributor:**
ATCC®

**Product Description:**

**Virus Classification:** *Flaviviridae, Flavivirus*  
**Species:** Japanese encephalitis virus (JEV)  
**Strain/Isolate:** Okayama *Culex tritaeniorhynchus* (OCT)-541, line 35-24  
**Original Source:** OCT-541, line 35-24 is reported to be an attenuated derivative of OCT-541. It was derived by rapid passage of the parent strain at incubation temperatures between 35 and 24° over 30 passages in hamster kidney cells. The attenuation of this preparation of OCT-541, line 35-24, has not been confirmed by BEI Resources. OCT-541 was isolated in 1948 from mosquitoes (*Culex tritaeniorhynchus*) in Japan.  
**Comments:** JEV, OCT-541, line 35-24 was deposited at the ATCC® by Dr. William M. Hammon of the Department of Epidemiology and Microbiology, Graduate School of Public Health, University of Pittsburgh, Pittsburgh, Pennsylvania.

JEV is an arbovirus transmitted in a zoonotic cycle among rice-field mosquitoes of the *Culex* species, with pigs as amplifying hosts and wading birds as intermediate hosts. It is the most important cause of epidemic encephalitis worldwide, with around 50,000 cases and 10,000 deaths per year affecting essentially children below 10 years of age. Approximately half the survivors have severe neurological disabilities. Most cases occur in rural areas of Southeast Asia, but the geographical area affected by JEV is expanding. Around 50,000 cases and 10,000 deaths per year are attributed to JEV in Southeast Asia. Further spread in other parts of the world is potential for exposure to infectious JEV.  

**Biosafety Level:** 3  
**Disclaimers:**  
You are authorized to use this product for research use only. It is not intended for human use.

Use of this product is subject to the terms and conditions of the BEI Resources Material Transfer Agreement (MTA). The MTA is available on our Web site at www.beiresources.org.

While BEI Resources uses reasonable efforts to include accurate and up-to-date information on this product sheet, neither ATCC® nor the U.S. Government make any warranties or representations as to its accuracy. Citations from scientific literature and patents are provided for informational purposes only. Neither ATCC® nor the U.S. Government warrants that such information has been confirmed to be accurate.

This product is sent with the condition that you are responsible for its safe storage, handling, use and disposal. ATCC® and the U.S. Government are not liable for any damages or injuries arising from receipt and/or use of this product.

**Material Provided:**  
Each vial contains approximately 1 mL of cell lysate and supernatant from hamster kidney cells (HaK; ATCC® CCL-15™) infected with JEV, OCT-541, line 35-24.

This virus, grown in Vero cells, is available as BEI Resources NR-9565.

**Note:** If homogeneity is required for your intended use, please purify prior to initiating work.

**Packaging/Storage:**  
NR-91 was packaged aseptically in screw-capped plastic cryovials. The product is provided frozen and should be stored at -60°C or colder immediately upon arrival. For long-term storage, the vapor phase of a liquid nitrogen freezer is recommended. Freeze-thaw cycles should be avoided.

**Growth Conditions:**

**Host:** HaK cells (ATCC® CCL-15™)  
**Growth Medium:** Minimum Essential Medium containing Earle's salts and non-essential amino acids supplemented with 2% irradiated fetal bovine serum, 2 mM L-glutamine and 1 mM sodium pyruvate, or equivalent (lot-specific details are on the Certificate of Analysis)  
**Infection:** Cells should be 80-90% confluent (not 100% confluent)  
**Incubation:** 6 to 9 days at 30°C and 5% CO₂  
**Cytopathic Effect:** Cell rounding and sloughing
